Lecture Notes 3: Sampling, Simulation, Low-Level Extensions

Sampling from Distributions

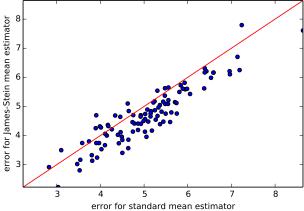

```
In [1]: import numpy,numpy.random
  Sampling from a uniform distribution between 0 and 1
In [2]: print numpy.random.uniform(0,1,[10])
[ \ 0.93954568 \ \ 0.32238431 \ \ 0.75696949 \ \ 0.90049416 \ \ 0.26976452 \ \ 0.50369415
  0.38062712 0.5703674
                            0.14836382 0.57742234]
   Sampling from normal distibution of mean 10 and standard deviation 0.01
In [3]: print numpy.random.normal(10,0.01,[10])
[ 10.0003412
                 9.99498074
                               9.99378432
                                             9.99055218 10.02652301
  10.00138163
                 9.97837911 10.00499227
                                             9.97606145
                                                           9.98383529]
```

Demo 1: Testing A Statistical Paradox (the James-Stein Paradox)

When estimating the mean of a data distribution, moving the estimator from the empirical mean, and closer to some arbitrary point (e.g. the origin) makes the estimator more accurate. Let's verify it:

```
In [4]: # Testing many times:
       errstd = []
       errstd2 = []
       n = 10
       d = 50
       for i in range(100):
            # sample from a distribution of mean vector 1 and standard deviation 1
            m = 1.0
            X = numpy.random.normal(m,1,[n,d])
            # empirical mean
            m_emp = X.mean(axis=0)
            # some coefficient
            c = (1-(d-2)*1.0/n/((m_emp)**2).sum())
            # james-stein estimator
            m_js = c*m_emp
            # the error between the true mean and the standard estimator
            errstd += [((m - m_emp)**2).sum()]
            # the error between the true mean and the said better estimator
            errstd2 += [((m - m_js)**2).sum()]
```

```
In [5]: import matplotlib
        from matplotlib import pyplot as plt
        %matplotlib inline
        from IPython.display import set_matplotlib_formats
        set_matplotlib_formats('pdf','png')
       plt.rcParams['savefig.dpi'] = 90
In [7]: plt.scatter(errstd,errstd2)
        1,h = min(errstd+errstd2),max(errstd+errstd2)
       plt.plot([1,h],[1,h],color='red')
        plt.xlabel('error for standard mean estimator')
        plt.ylabel('error for James-Stein mean estimator')
       plt.axis([1,h,1,h])
Out[7]: [2.2284672034412716,
        8.6388907351316337,
         2.2284672034412716,
         8.6388907351316337]
```

Observation: most points are below the curve (i.e. James-Stein estimator is better).

Making discrete choices

Let us suppose we have 7 fruits to choose from:

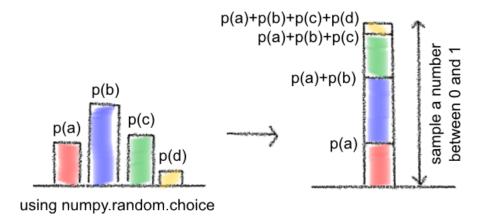

```
In [8]: fruits = ['watermelon', 'apple', 'grape', 'grapefruit', 'lemon', 'banana', 'cherry']
We use the function random.choice to randomly choose from that list
```

```
grape
```

The function choice of the module numpy.random provides some more functionalities such as choosing repeatedly

Another way to make discrete choices

```
In [13]: # Define fruits probabilities
    p = [0.05,0.70,0.05,0.05,0.05,0.05,0.05]

# Cumulate them
    1 = numpy.cumsum([0]+p[:-1]) # lower-bounds
    h = numpy.cumsum(p) # upper-bounds

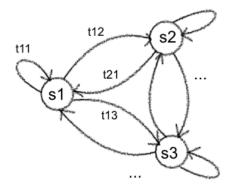

# Draw a number between 0 and 1
    u = numpy.random.uniform(0,1)
```

```
# Find which basket it belongs to
         s = (u>1)*(u<h)
         # retrieve the label
         fruits[numpy.argmax(s)]
Out[13]: 'apple'
  The code can be parallelized to choose multiple fruits at the same time
In [14]: # generate many numbers between 0 and 1
         u = numpy.random.uniform(0,1,[20])
         # find the basket to which they belong
         na = numpy.newaxis
         s = (u[:,na]>1[na,:])*(u[:,na]<h[na,:])
         print([fruits[i] for i in numpy.argmax(s,axis=1)])
['watermelon', 'apple', 'apple', 'apple', 'apple', 'watermelon', 'apple', 'apple', 'apple', 'apple', 'a
   More importantly, the code can be parallelized to choose from multiple distributions at the same time. Let us
create a matrix of probability distributions.
In [15]: P = [
             [0.0,0.05,0.05,0.05,0.05,0.05,0.70,0.05],
             [0.0,0.05,0.05,0.70,0.05,0.05,0.05,0.05]
         # (note that we have added a zero-probability state
         # at the beginning for ease of implementation)
  We stack them, and compute the bounds L and H
In [16]: C = numpy.cumsum(P,axis=1) # lower-bounds
         L,H = C[:,:-1],C[:,1:]
  Draw 8 fruits from each distribution, and test the bounds
In [17]: R = numpy.random.uniform(0,1,[3,8])
         S = (R[:,:,na] > L[:,na,:])*(R[:,:,na] < H[:,na,:])
In [18]: for s in S:
             print([fruits[i] for i in numpy.argmax(s,axis=1)])
['cherry', 'cherry', 'lemon', 'grapefruit', 'grape', 'cherry', 'cherry', 'cherry']
['apple', 'banana', 'banana', 'banana', 'apple', 'banana', 'banana']
```

Demo 2: Monte Carlo Simulation of a Markov Chain

A Markov chain transits between a set of states, where the transition between pairs of states is associated with a fixed probability. The set of probabilities can be stored in a transition matrix.

['grape', 'grape', 'grape', 'grapefruit', 'grape', 'grape', 'apple', 'grape']

Thanks to our parallel implementation, we can choose from multiple probability distributions, and thus, simulate multiple markov chains in parallel, each of them being in a different state.

```
In [20]: # Add empty state to transition matrix
        P = numpy.pad(T,1,mode='constant')[1:-1,:-1]
        print(P)
[[ 0.
       0.9 0.1 0. ]
ΓО.
       0.
            0.9 0.17
 Γ0.
                 0.]]
In [21]: # Implementing transition for each particle
         def mcstep(X):
             Xp = numpy.dot(X,P)
             Xc = numpy.cumsum(Xp,axis=1)
             L,H = Xc[:,:-1],Xc[:,1:]
             R = numpy.random.uniform(0,1,[len(Xp),1])
             return (R > L)*(R < H)*1.0
In [22]: # Initialize all particles to state 1
         A = numpy.outer(numpy.ones([30]),[1.0,0,0])
         print 'initial distribution of particles states: [%.3f %.3f %.3f]'%tuple(A.mean(axis=0))
         for i in range(20):
                 print '(iter %2d)'%i,numpy.argmax(A,axis=1)
                 A = mcstep(A)
         # Print distribution of sampled states
         print 'final distribution of particles states: [%.3f %.3f %.3f]' %tuple(A.mean(axis=0))
```

```
initial distribution of particles states: [1.000 0.000 0.000]
(iter 2) [0 1 0 1 0 0 0 0 0 0 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0 0 1 0 0]
(iter 8) [1 0 1 1 0 0 0 0 1 0 1 0 0 0 1 1 1 0 0 0 0 0 1 0 1 0 1 0 0 0 1]
(iter 10) [1 1 1 0 1 0 0 0 1 0 1 0 1 1 1 1 1 0 0 0 0 0 1 1 1 1 1 1 0 0 1]
(iter 11) [1 1 1 0 1 0 0 0 1 0 1 0 1 1 1 1 1 0 0 0 0 0 1 1 1 1 1 1 1 1 1]
(iter 15) [1 1 1 1 1 0 0 0 1 0 1 0 1 1 1 0 1 1 0 0 1 1 0 0 1 1 0 0 0 1 0 0 0]
final distribution of particles states: [0.533 0.433 0.033]
```

Low-level extensions

Idea: Write highly optimized functions directly in C/C++, Fortran, or Cuda, and make them accessible to the Python user. Numpy is also based on this principle: making very efficient functions accessible in Python in a user-friendly manner.

Example: F2PY (Fortran to Python)

Main steps:

- Install gfortran (fortran compiler) and f2py (binding between Fortran and Python)
- Create file (e.g. convolution.f90) containing some optimized code for convolutions.
- Compile convolution.f90 into a Python module using f2py
- Import module convolution directly from Python.

Applying batch convolutions

We run the command

We would like to use the following Fortran code that computes a batch of convolutions in the same way as the convolutional layer of a neural network.

Figure 1: file: convolution.f90

Demo 3: Filtering images to detect interesting features

```
# horizontal edge detector in reverse direction
         W[:2,:,:,1] = -1.0
         W[2:,:,:,1] = 1.0
         # vertical edge detector
         W[:,:2,:,2] = 1.0
         W[:,2:,:,2] = -1.0
         # vertical edge detector in reverse direction
         W[:,:2,:,3] = -1.0
         W[:,2:,:,3] = 1.0
         # more red than yellow detector
         W[:,:,0,4] = 1.0
         W[:,:,1,4] = -1.0
In [27]: Z = convolution.conv(X,W)
         Y = numpy.maximum(0,Z)
In [28]: f = plt.figure(figsize=(10,7))
         for i in range(4):
             p = f.add_subplot(2,2,i+1)
             p.imshow(Y[:,:,i])
                                               100
                                               150
                                               250
                        150
                                               150
                        200
                                               200
                        250
                                               250
```

In [29]: plt.imshow(Y[:,:,4])

Out[29]: <matplotlib.image.AxesImage at 0x7f0dba528dd0>
